ModelIt!

Teacher's Guide

Building a Space Elevator: The Ultimate Engineering Challenge

Modeling the Physics and Materials Science of a Tether to the Stars

Quick Reference

Grade Level	Grade 10L3
NGSS Standard	HS-PS2-2, HS-PS1-3
Time	45–60 minutes (core lesson)
Materials	Student Activity Pack, devices with ModelIt! access
Prep	Print activity packs, test ModelIt! on student devices
Grouping	Partners or small groups (2–4)

© 2026 Discovery Collective. All rights reserved. For teacher use only.

ModelIt!

Performance Expectation: HS-PS2-2, HS-PS1-3

Use mathematical representations to support the claim that the total momentum of a system of objects is conserved when there is no net force on the system. Plan and conduct an investigation to gather evidence to compare the structure of substances at the bulk scale to infer the strength of electrical forces between particles.

Three-Dimensional Learning

Science Practice	**Using Mathematics and Computational Thinking** — Students use mathematical models to calculate gravitational force gradients, centrifugal forces, cable stress profiles, and material requirements along the full length of a space elevator.
Disciplinary Core Idea	**PS2.A Forces and Motion / PS1.A Structure and Properties of Matter** — Students analyze how gravitational and centrifugal forces create a non-uniform stress profile along the cable, and how the atomic-scale structure of carbon nanotubes determines bulk material strength.
Crosscutting Concept	**Scale, Proportion, and Quantity** — Students grapple with extreme scales — a cable spanning 100,000+ km, material properties measured at the atomic level, forces varying over four orders of magnitude — and analyze how scaling relationships determine feasibility.

CAST Testing Alignment

MULTIPLE CHOICE:

A space elevator cable must support its own weight from the surface to geostationary orbit (35,786 km). The gravitational force decreases with altitude squared while centrifugal force increases linearly. According to your model, at what altitude does the cable experience maximum stress, and why?

CONSTRUCTED RESPONSE:

Using your model, explain why the space elevator is often described as 'one material breakthrough away from reality.' Address the specific gap between theoretical carbon nanotube properties and manufacturing capabilities, and evaluate whether this gap is likely to be closed within 25 years.

2 Scoring Rubric

ModelIt!

Assessment Reference

This is the same rubric students see in their Activity Pack. Use it during and after the lesson for formative and summative assessment. Circle or highlight the proficiency level for each skill.

Skill	Expert (4)	Proficient (3)	Developing (2)	Beginning (1)
Identifying Components	EXPERT Correctly identifies and sorts ALL components as internal or external with detailed reasoning	PROFICIENT Correctly identifies and sorts MOST components with some reasoning	DEVELOPING Identifies components but has difficulty sorting or explaining	BEGINNING Needs significant help identifying components
Establishing Relationships	EXPERT Accurately describes ALL positive and negative relationships with clear evidence	PROFICIENT Accurately describes MOST relationships with some evidence	DEVELOPING Identifies some relationships but struggles with direction	BEGINNING Needs help understanding how components connect
Running Simulations	EXPERT Makes accurate predictions AND explains surprising results using evidence	PROFICIENT Makes reasonable predictions and records clear observations	DEVELOPING Runs simulations but predictions or observations are incomplete	BEGINNING Needs help running simulations or recording data
Explaining Results	EXPERT Uses multiple pieces of evidence to explain HOW and WHY systems interact	PROFICIENT Uses evidence to explain system interactions	DEVELOPING Gives partial explanations with limited evidence	BEGINNING Needs help connecting evidence to explanations

Scoring Guidance

Expert (4): Student demonstrates deep understanding and can transfer knowledge to new contexts.
Proficient (3): Student meets grade-level expectations and shows solid understanding.
Developing (2): Student is making progress but needs additional scaffolding or practice.
Beginning (1): Student needs significant support; consider using Differentiation strategies (Section 7).

3 Background Content Knowledge

ModelIt!

For Your Confidence

This section provides the science background you need to facilitate this lesson with authority. You don't need to teach all of this — it's here so you can answer student questions accurately.

In 1895, Russian scientist Konstantin Tsiolkovsky imagined a tower reaching from Earth's surface to geostationary orbit — inspired by the newly built Eiffel Tower. In 1979, Arthur C. Clarke popularized the concept in his novel 'The Fountains of Paradise.' Today, the space elevator remains one of the most tantalizing engineering concepts ever proposed: physically sound, mathematically proven, and economically transformative — blocked solely by the absence of a material strong enough to build the cable.

The Physics of the Space Elevator

A space elevator exploits the balance between gravity and centrifugal force at geostationary orbit. Below 35,786 km, gravity pulls the cable downward. Above this altitude, centrifugal force (from Earth's rotation) pulls the cable outward. A counterweight beyond geostationary orbit keeps the entire system taut. The cable does not need to be launched into orbit — it is in equilibrium, held vertical by the same physics that keeps geostationary satellites stationary. The concept is as solid as gravity itself.

The Materials Crisis

The problem is deceptively simple: the cable must support its own weight. But across 36,000+ km, even the lightest, strongest materials accumulate enormous self-weight. Steel would need a cross-section at the top that is impossibly large (taper ratio of 10^14). Kevlar is better but still requires a taper ratio of millions. Only carbon nanotubes — with theoretical tensile strength of 100+ GPa and density of 1.3 g/cm^3 — have the strength-to-weight ratio that makes the taper ratio manageable (about 1.6). But here is the catch: individual nanotubes are centimeters long. The cable needs to be 100,000+ km. And defects in real manufactured nanotube fibers reduce their strength by 50-100 times below theoretical values.

Manufacturing the Impossible

Bridging the gap from centimeter-length perfect nanotubes to 100,000-km structural cable requires several breakthroughs: growing defect-free nanotubes to meter and then kilometer lengths, spinning them into fibers that transfer load between individual tubes efficiently, maintaining structural quality at manufacturing scale, and doing all of this at a cost that makes the elevator economically viable. Progress is being made — nanotube fibers have improved from 0.1 GPa to 1-2 GPa over two decades — but the target of 50+ GPa remains distant.

The Economic Transformation

Current rocket launch costs are $2,000-10,000 per kilogram to low Earth orbit (with SpaceX Starship targeting $200/kg). A space elevator could deliver payload to geostationary orbit — much higher and more valuable — for potentially under $200/kg using only electrical energy for the climber. At this cost, space solar power, orbital manufacturing, lunar and asteroid mining, and routine space tourism all become economically viable. A space elevator would not just reduce launch costs — it would fundamentally transform humanity's relationship with space, the same way railroads transformed continents.

4 The LEVER Framework

ModelIt!

About LEVER

LEVER is how every ModelIt! lesson works. Students move through five phases to build, test, and refine a computational model. Each lesson is self-contained — students complete all five phases in one session.

L **Locate the System**

Students identify ten key components of the space elevator system: cable tensile strength, gravitational force gradient, centrifugal counterweight, climber mass, orbital altitude, material limits, energy consumption, payload capacity, atmospheric stress, and economic viability.

E **Establish Relationships**

Students map relationships showing that cable tensile strength versus gravitational force gradient determines whether the cable can support itself, climber mass determines the additional strength margin needed, and material limits represent the gap between what physics requires and what manufacturing delivers.

V **Visualize & Model**

Students build a computational model showing the ten-component space elevator system with the materials gap as the central constraint.

E **Evaluate Outcomes**

Students run carbon nanotube ideal, current materials, and climber stress test scenarios to identify the exact material property threshold where the space elevator transitions from impossible to feasible.

R **Revise & Extend**

Students add orbital debris risk, climber power system, or anchor station design to model more complete space elevator engineering challenges.

Dropping ModelIt! Into Your Existing Unit

ModelIt! is a **supplement**, not a replacement for your science curriculum. Each lesson stands alone, but it becomes even more powerful when students revisit their model throughout a unit. Here are easy ways to weave it in:

At the start of a unit	Use this lesson to introduce the phenomenon. Students build a “first draft” model based on what they already know. Save it.
After a reading or lab	Have students reopen their model and update it: “Based on what you just learned, would you add a component? Change a relationship?” Takes 10–15 minutes.
As a “what-if” tool	When students ask questions during class, say: “Great question — go test that in your model!” Students run new scenarios and report back.
For peer discussion	Partners compare models: “Why does your model have this arrow and mine doesn’t?” Differences spark scientific debate using evidence.
As a presentation tool	Students project their model and walk the class through it live — showing components, running scenarios, answering audience “what-if” challenges in real time.
At the end of a unit	Compare Day 1 model to final model. The growth IS the assessment — students see how their thinking evolved.

5 Slide-by-Slide Facilitation

ModelIt!

Slide 1: Cover

2 min

Say: *"Imagine a cable stretching from a platform in the Pacific Ocean, through the clouds, through the atmosphere, past the International Space Station, all the way to geostationary orbit 36,000 km up. Now imagine riding an elevator up it. That is not science fiction — the physics works perfectly. There is only one problem."*

Watch For

Show a scale visualization of the space elevator — Earth to geostationary orbit. Then reveal the problem: no material exists that is strong enough. Yet. Let the challenge hook students.

Slide 2: Learning Objectives

3 min

Say: *"Today you are tackling the most audacious engineering concept in human history — a structure 100,000 km long, held up by the balance between gravity and centrifugal force, blocked by one single materials science problem."*

Watch For

Have students read objectives. Pre-teach 'geostationary orbit' and 'tensile strength-to-weight ratio.' Use the fishing line analogy: imagine a fishing line that must support its own weight over 36,000 km.

Slide 3: Big Question

3 min

Say: *"The physics says yes. The engineering says yes. The economics say it would transform civilization. The materials science says... not yet. What would it take?"*

Watch For

Quick-write: Students estimate how strong a material would need to be to support its own weight over 36,000 km. Share out guesses. Then reveal the actual number — most will be shocked.

Slide 4: LEVER Framework

2 min

Say: *"We are building a model of a structure spanning from sea level to beyond geostationary orbit. The forces change at every altitude. The challenge is whether any material can survive them all simultaneously."*

Watch For

Preview LEVER steps. Emphasize the extreme scale — this model spans 100,000+ km and forces from 0 to 9.8 m/s^2.

Slide 5: Activity 1: Components

8 min

Say: *"Ten variables. Three you set through design choices — material, counterweight, and climber mass. Seven that physics and economics determine. Can you find a configuration that works?"*

Watch For

Guide students through all ten components. Spend extra time on Cable Tensile Strength and Material Limits — the gap between these two numbers is the entire story.

Slide 6: Activity 2: Connections

8 min

Say: *"Gravity pulls the cable down. Centrifugal force pulls it up. Somewhere in between, the stress is maximum. If the cable cannot handle that stress, the whole thing breaks. Every other variable flows from this single material requirement."*

Watch For

Help students map the force balance along the cable. Show how taper ratio reduces stress but increases total mass. Identify the peak stress point at geostationary orbit.

Slide 7: Activity 3: Simulation

10 min

Say: *"What happens when you try to build a space elevator with the strongest material we can actually make? Let us find out."*

Watch For

Students predict system feasibility for each scenario. The current materials scenario should be a powerful demonstration of the gap. The ideal nanotube scenario shows the vision.

Slide 8: Discoveries

5 min

Say: *"The space elevator is one materials science breakthrough away from reality. That breakthrough would reduce the cost of reaching orbit by 10 to 50 times and transform humanity's relationship with space. The question is: when — not if — someone solves the manufacturing problem."*

Watch For

Lead discussion connecting the model to real materials science progress. Show the trajectory of nanotube strength improvement over the past 20 years. Extrapolate — when might we reach the threshold?

Slide 9: STEM Challenge

12 min

Say: *"You have $10 billion and 25 years. Design the research roadmap that gets us from today's 1-2 GPa nanotube fibers to the 50+ GPa needed for a space elevator. What is your plan?"*

Watch For

Groups design comprehensive research roadmaps with milestones, decision points, and contingency plans. Present timelines with justification from materials science knowledge. Class evaluates feasibility.

6 Answer Key & Expected Responses

ModelIt!

Component Sorting

- **EXTERNAL:** Cable Tensile Strength, Centrifugal Counterweight, Climber Mass
- **INTERNAL:** Gravitational Force Gradient, Orbital Altitude, Material Limits, Energy Consumption, Payload Capacity, Atmospheric Stress, Economic Viability

Relationships

- **Cable Tensile Strength to Payload Capacity:** POSITIVE (+) — Stronger cable material means more margin beyond self-support, allowing heavier climbers and larger payloads. Each increase in material strength translates directly to increased useful carrying capacity for the elevator system.
- **Gravitational Force Gradient to Cable Tensile Strength:** POSITIVE (+) — The varying gravitational pull creates non-uniform stress along the cable — maximum at geostationary orbit where accumulated weight from below and centrifugal tension from above converge. The cable material must exceed this peak stress with a safety margin, which sets the minimum required tensile strength.
- **Payload Capacity to Economic Viability:** POSITIVE (+) — Higher payload capacity per climber trip reduces the cost per kilogram delivered to orbit, improving economic viability. If each trip delivers 20 tons instead of 5 tons, the fixed infrastructure cost is amortized over four times more cargo, driving the per-kilogram price toward the transformative sub-$200 target.

Key Discoveries

- The space elevator concept is physically sound — the math works, the orbit mechanics are well understood, and the engineering design is feasible in principle — the sole blocking obstacle is materials science
- The strength-to-weight ratio gap is approximately 50-100 times — current manufacturable carbon nanotube fibers achieve 1-2% of the theoretical strength needed, and closing this gap is one of the greatest challenges in materials science
- Cable taper ratio — making the cable thickest at geostationary orbit where stress peaks — dramatically reduces total mass requirements but still demands materials that cannot currently be manufactured at the needed quality and length
- If the materials challenge were solved, a space elevator would reduce the cost of reaching orbit from thousands of dollars per kilogram to potentially under $200 per kilogram — fundamentally transforming access to space

7 Collaborative Learning Protocols

ModelIt!

Why This Matters

ModelIt! is a digital tool, but the deepest learning happens between humans. Computational modeling is most powerful when students build understanding *together* — debating relationships, challenging predictions, and constructing explanations as a community. These protocols ensure every student's voice is part of the model. Use at least ONE per lesson.

Model Gallery Walk

When: After students build models (LEVER Phase V)
Setup: Groups post their models on screens/desks. Half the class stays to "defend," half rotates with sticky notes.
Protocol: Visitors leave 2 sticky notes: one "I notice..." and one "I wonder..." After rotation, defenders read feedback aloud. Class discusses patterns.
Why it works: Students see that the SAME phenomenon can be modeled differently — and that's how real science works. (Bandura: learning through observation of peers)

Scientist Fishbowl

When: During simulation discussion (LEVER Phase E)
Setup: 4-5 students sit in center circle. Rest of class observes with clipboards.
Protocol: Inner circle discusses: "What happened in Scenario 3 and WHY?" using only evidence from their models. Outer circle records strongest arguments. Swap groups.
Why it works: Students practice scientific discourse without teacher directing. Observers learn to evaluate arguments. (Freire: dialogue as the foundation of critical consciousness)

Component Jigsaw

When: During component analysis (LEVER Phase L)
Setup: Assign each group ONE component to become "experts" on. They research it, discuss it, draw it.
Protocol: Regroup so each new team has one expert per component. Experts teach their component to the team. Team builds the model together using everyone's expertise.
Why it works: Every student is essential — the model literally cannot be built without each person's knowledge. Interdependence drives engagement. (Lave & Wenger: learning through legitimate peripheral participation)

Prediction Debate

When: Before running simulations (LEVER Phase E)
Setup: Post a scenario. Students physically move to corners: "Fire Spread will INCREASE a lot" / "INCREASE a little" / "STAY the same" / "DECREASE."
Protocol: Each corner group has 2 minutes to build their argument using model logic. One spokesperson presents. Then RUN the simulation. Losing corners explain what they missed.
Why it works: Movement + social risk + immediate feedback. Students CARE about the outcome because they committed publicly. Wrong predictions become the best learning moments.

Pair Programming for Models (Digital Collaboration)

When: Throughout model building
Setup: Two students, one device. **Driver** controls the mouse/keyboard. **Navigator** directs strategy and catches errors. Switch every 5 minutes.
Protocol: Navigator must verbalize every decision: "I think we should add a negative arrow from Rainfall to Dry Vegetation because..." Driver cannot act without Navigator's reasoning.
Why it works: Forces articulation of scientific thinking. The model becomes a shared artifact, not an individual assignment. Students who struggle with writing can demonstrate understanding verbally. Borrowed from computer science — where the best code is written in pairs.

Quick Protocol Selection Guide

Short on time (5 min)	Prediction Debate — gets bodies moving, generates energy fast
Full period available	Component Jigsaw — deep collaboration, every student contributes

After simulation day	Model Gallery Walk — peer feedback, multiple perspectives
Advanced discussion	Scientist Fishbowl — builds academic discourse skills
Every day default	Pair Programming — transforms individual work into dialogue

8 Differentiation & Extensions

ModelIt!

Below Grade Level

- Pre-sort components as a whole class
- Provide sentence frames for relationships
- Use visual vocabulary cards
- Pair with a strong reader

Advanced Learners

- Add 2-3 additional components
- Research real-world data
- Create multi-step causal chains
- Compare to similar systems globally

English Language Learners

- Pre-teach key vocabulary
- Provide bilingual glossary
- Use visual supports with text
- Allow verbal responses

Gifted & Talented

- Create feedback loop diagrams
- Research prevention strategies
- Write a policy brief
- Connect to climate change

9 Common Misconceptions

ModelIt!

Why This Matters

Addressing misconceptions proactively helps students build accurate scientific understanding. Use these as formative assessment checkpoints during the lesson.

STUDENTS MAY THINK	SCIENTIFIC UNDERSTANDING
"A space elevator cable would need to be incredibly thick and heavy"	With the right material, the cable could be remarkably thin — perhaps a few centimeters wide at the base, tapering to thicker at geostationary orbit, and narrowing again above. Carbon nanotubes at theoretical strength have such a high strength-to-weight ratio that the taper ratio is only about 1.6, meaning the widest point is less than twice the width of the narrowest. Total cable mass might be only thousands of tons — heavy by everyday standards but manageable by industrial standards. The problem is not weight or size — it is the material strength needed to achieve this compact design.

STUDENTS MAY THINK	SCIENTIFIC UNDERSTANDING
"The space elevator would float or fall without constant energy input"	A space elevator is not floating — it is in orbital equilibrium. Below geostationary orbit, gravity pulls the cable down. Above, centrifugal force from Earth's rotation pulls it up. The system is balanced like a ball on a hilltop — it stays in place without any energy input. The only energy needed is for the climbers traveling up and down. If power were cut, the cable would remain in place indefinitely (assuming no perturbations). This is fundamentally different from an aircraft, which falls without thrust.

STUDENTS MAY THINK	SCIENTIFIC UNDERSTANDING
"We could just use really strong steel or Kevlar"	The strength-to-weight ratio is what matters, not just strength. Steel has high tensile strength (2 GPa) but is very dense (7.8 g/cm^3), giving a poor strength-to-weight ratio. A steel space elevator cable would need a taper ratio of 10^14 — the cable would be wider than the observable universe at its thickest point. Kevlar improves the ratio but still requires astronomical taper. Only materials with both extreme strength AND low density — like carbon nanotubes (100+ GPa, 1.3 g/cm^3) — produce manageable taper ratios. This is why the space elevator is specifically a nanomaterials challenge, not just a structural engineering challenge.
